

Why ROC curve?

- Reason 1:- threshold selection of classification
- Reason 2:- AUC-ROC: by using this we can compare two model by measuring area under curve (AUC) under ROC

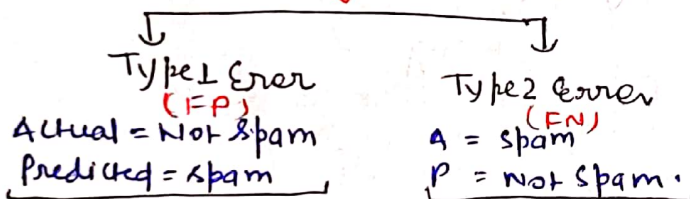

Normally while giving classification prediction Model give probability of being (0 or 1)

we as Data Scientist has to decide what will be threshold (0.5, 0.7 or 0.6)
 → to put Probability in target class (0, or 1)

Ex

Model error

on threshold = 0.5

↓
 this more dangerous

↓
 to solve this. ⇒ we will adjust our threshold such a way that

this way we can handle our Precision & recall value with our intuition.

Q. how we will get correct threshold for our business problem?

→ this answer will be provided by ROC Curve

represents with given model & 1
True Positive Rate (TPR) → Benefit

$$TPR = \frac{TP}{TP + FN} = \frac{\text{Predicted positive}}{\text{Total Actual positive}}$$

	Pred	
Act	TP	FN
	FP	TN

TPR is also known as benefit i.e. we made system to get benefit i.e. nothing be TPR

अनुपेक्षा करता Model & 1

False Positive Rate (FPR) → Cost (Loss)

$$FPR = \frac{FP}{FP + TN} = \frac{\text{Wrongly Predicted positive}}{\text{Total Actual Negative}}$$

Ex:- out of all "Not Spam" how many predicted as "Spam"

Summary

Best Case

TPR = 100% → when FN = 0

FPR = 0% → when FP = 0

100	0
0	100

ROC curve

→ plotting curve b/w TPR & FPR for diff-diff threshold to decide which threshold is giving max^m TPR & least FPR.

if this threshold is giving max^m TPR then we will select this threshold.

Different Cases of threshold

threshold (\downarrow) \rightarrow $\begin{matrix} \text{TPR} \\ \text{FPR} \end{matrix}$ \rightarrow both (\uparrow)

threshold (\uparrow) \rightarrow $\begin{matrix} \text{TPR} \\ \text{FPR} \end{matrix}$ \rightarrow both (\downarrow)

this conclude that relation
between TPR & FPR is
linear

but

completely wrong conception

X but we
don't have
such kind
of relation
actually.

✓ we have
this kind of
relationship
having TPR &
FPR

AUC-ROC

The AUC-ROC measures the entire 2-D
area under the entire ROC curve
from (0,0) to (1,1).

\rightarrow If $AUC = 1 \Rightarrow$ model is perfect.

\rightarrow If $AUC = 0.5 \Rightarrow$ model has no discrimi-
nation ability. it is as good as
random guessing

\rightarrow If $AUC = 0 \Rightarrow$ Model is perfectly
wrong.

• AUC usually ranges from [0.5, 1]
i.e. 0.5 (random) & 1 (perfect) with
higher values indicating better
classification performance.

Practicle code to find

finding probability

$y_prob = \text{model.predict_proba}(x_test)[i]$

finding threshold, fpr, tpr ?

from sklearn.metrics import roc_curve

fpr, tpr, threshold = roc_curve(y_test, y_prob)

It will return FPR & TPR for
each threshold.
